26 1.1. Methods

27 1.2. Chalcone Synthesis reaction

28 The Claisen-Schmidt condensation typically involves equimolar quantities of the  
29 benzaldehyde and an acetophenone in the presence of alcoholic alkali (Scheme 1):

31 **Scheme S1.** Chalcone synthesis by classic base-catalysed reaction (Claisen-Schmidt).

32

33 1.3. KAZ3 structure characterization

34 The structure of the formed chalcone was confirmed using an array of different  
35 analytical methods including nuclear magnetic resonance (NMR), mass spectroscopy  
36 (MS), Fourier transform infrared spectroscopy (FTIR) and thin layer chromatography  
37 (TLC). The <sup>1</sup>H-NMR and <sup>13</sup>C-NMR spectra were recorded on a 400 MHz super-  
38 conducting Bruker Spectrometer at 30 °C. Tetramethylsilane (TMS) was used as an  
39 internal standard. Chemical shifts are reported in δ units relative to the TMS signal and  
40 coupling constants (*J*) expressed in Hertz (Hz). <sup>1</sup>H-NMR information is provided in the  
41 following format: number of protons, multiplicity, coupling constant (where necessary)  
42 and assignment. Multiplicities are reported as follow; s=singlet, d=doublet, t=triplet,  
43 q=quartet, dd=doublets of doublet, m=multiplet. Infrared spectra (IR) were recorded  
44 using potassium bromide disks on a Perkin-Elmer 298 Spectrophotometer. Mass  
45 spectra and Accurate mass were recorded on a Micromass Quattro II Low Resolution  
46 Triple Quadruple Mass Spectrometer (EPSRC National Mass Spectrometry Service  
47 Centre, Swansea UK). Melting points (uncorrected) were determined on a Gallenkamp  
48 melting point apparatus in open glass capillary tubes. Thin layer chromatography (TLC)  
49 was performed on Merck Aluminium Sheet Silica Gel 60f<sub>254</sub> coated plates. The TLC

50 plates visualised under Multiband UVGL-58 UV-254/366 nm UV light and stained  
51 with 2,4-dinitrophenylhydrazine (DNP to stain for the carbonyl group) or iodine  
52 absorbed on sand or phosphomolybdic acid (PMA). Silica gel (Fluka Silica 60; standard  
53 30-45  $\mu$  fine grade 20-45  $\mu$ ) was used for Flash Column Chromatography. Elemental  
54 analyses (CHN) were performed on a CE440 elemental analyser by Warwick Analytical  
55 Services and were within  $\pm 0.4$  % of the theoretical values, unless otherwise stated.

56

#### 57 1.4. Structural characterization of silica hosts

58 The small angle X-ray scattering (SAXS) patterns of the mesoporous silica samples  
59 (MCM-41, SBA-15) were recorded on a Rigaku R-AXIS IV Imaging Plate Detector  
60 mounted on a Rigaku RU-H3R Rotating Copper Anode X-ray Generator ( $\lambda=1.54$  Å).  
61 The pore structure of SBA-15 and MCM-41 silica samples was studied by means of N<sub>2</sub>  
62 adsorption-desorption isotherms at 77 K. The experiments were performed on an  
63 automated manometric instrument (Autosorb-1MP, Quantachrome Instruments) after  
64 outgassing the samples (~30 mg) at 250 °C overnight under high vacuum. BET areas  
65 were calculated by the pertinent approximation and consistency criteria [42], while the  
66 pore volumes of MCM-41 and SBA-15 samples were determined from the N<sub>2</sub> uptake  
67 plateau value at high relative pressures ( $p/p_0 \sim 0.96$ ) by assuming that the adsorbed fluid  
68 has liquid N<sub>2</sub> density. Pore size distributions were deduced by using the N<sub>2</sub>-silica  
69 QSDFT (Quenched Solid Density Functional Theory) kernels.

70

#### 71 1.5. Preliminary drug concentration determination

72 A preliminary study was conducted to investigate the suitable drug concentration in the  
73 initial suspensions of mesoporous silica before conducting electrospraying or solvent  
74 impregnation as loading methods. SBA-15 (6 mg/mL) was suspended in different drug

75 solutions with three different drug concentrations (2 mg/mL, 6 mg/mL, 12 mg/mL).  
76 Both loading methods were applied on the prepared suspensions. The produced loaded  
77 formulations were analyzed for their drug content using UV spectrophotometry and  
78 drug crystallinity using XRD.

79

#### 80 1.6. Particle size distribution

81 The particle size distributions of SBA-15, MCM-41, FS and the drug loaded  
82 formulations were analysed using laser diffraction size analysis (NanoBrook Omni  
83 Particle Sizer and Zeta Potential Analyzer, Brookhaven Instruments, UK). Two mg of  
84 each sample were suspended in 2 mL distilled water and were sonicated for 5 minutes.  
85 The particle size distribution was an average of five repetitions. The average values of  
86 D10, D50 and D90 were taken as the mean diameter. The lognormal size distribution  
87 was used to determine the size uniformity by calculating the span value. The span value  
88 is a parameter that is used to assess the width of particle size distribution and was  
89 calculated using the following equation

$$90 \quad \text{Span} = \frac{D_{90}-D_{10}}{D_{50}} \quad [2]$$

91 Where D10, D50 and D90 are the sizes for which 10 %, 50 % and 90 % of the  
92 population (distribution) lies below, respectively. The higher the span value, the wider  
93 the particle size distribution.

94

#### 95 1.7. $\zeta$ -potential studies

96 Zeta potential of the pristine and the drug loaded samples was measured in phosphate  
97 buffer saline (PBS) solution. The zeta potential values of the silica particles dispersions  
98 in acetone and ethanol were also measured. All experiments were performed using

99 NanoBrook Omni Particle Sizer and Zeta Potential Analyzer (Brookhaven Instruments,  
100 UK) and were repeated three times.

101

## 102 1.8. Fourier transform infrared spectroscopy (FTIR)

103 Chemical bonding and interactions of MCM-41, SBA-15, FS and the drug loaded  
104 formulations were investigated using Perkin Elmer FTIR (Perkin Elmer with the  
105 software Bruker Alpha Opus 27). The IR spectra were obtained using the ATR  
106 technique (attenuated total reflection) on diamond crystal over the range of 4000 - 400  
107  $\text{cm}^{-1}$  after 30 scans with a resolution of 4  $\text{cm}^{-1}$ .

108

## 109 1.9. HPLC analysis

110 A Shimadzu HPLC system series LC-20A was used for drug quantification consisting  
111 of a LC-20AD module pump, a SIL-10ADVP auto sampler and a UV-Diode array  
112 detector adjusted at 346 nm. Elution was performed on a Discovery® HS C18 (15 cm  
113 x 4.6 mm, 5 $\mu\text{m}$ ) column using acetonitrile: water (60:40 v/v) as the mobile phase with  
114 a flow rate of 1.0 mL/min and an injection volume of 90  $\mu\text{L}$  at 346 nm. The calibration  
115 curve was linear ( $R^2 = 0.998$ ) in the concentration range evaluated (0.5 - 4  $\mu\text{g/mL}$ ).

116

## 117 2. Results

### 118 2.1. KAZ3 Structure characterization

119 The chemical structure of the drug is shown in figure S1. The purity of the product was  
120 determined by TLC and elemental analysis. The product was also characterized by  
121 proton & carbon-13 NMR, infrared spectroscopy and mass spectrometry. The trans  
122 geometry of the alkene double bond was confirmed using  $^1\text{H}$  NMR, where the alkene  
123 protons appeared as a characteristic set of two doublets between 6.0 - 8.0 ppm having

124 coupling constants between 15 and 20 Hz, typical of a trans isomer Figure S2A.  
125 Coupling constants for cis alkene protons are 5-12 Hz. Coupling constants indicate the  
126 interaction between nuclei transmitted through intervening electrons. Aromatic proton-  
127 proton spin coupling constants gave information of whether the coupling protons are in  
128 ortho (Jab 7-10 Hz), meta (Jab 2-3 Hz) or para position (Jab 0-1 Hz) to each other. The  
129 infrared spectrum of KAZ3 (Figure S2C) shows absorption bands at  $\sim 1650-1660\text{ cm}^{-1}$   
130 related to the  $\alpha, \beta$ -unsaturated carbonyl group ( $=\text{C}-\text{C}=\text{O}$ ), which is characteristic of  
131 chalcones. The vibration of the unsaturated C=C bond (enone group) resulted in an  
132 absorption peak at  $1590\text{ cm}^{-1}$ , while the absorption band of  $=\text{C}-\text{H}$  appeared at  $3005\text{ cm}^{-1}$   
133 <sup>1</sup>. The variance in absorption of the carbonyl group of chalcones is due to the presence  
134 of the electron donating methoxy groups in the phenyl ring. The asymmetrical  
135 stretching of the C-O-C bond in the methyl ether groups appeared around  $1260\text{ cm}^{-1}$   
136 with a symmetrical stretching band around  $1020\text{ cm}^{-1}$ . A distinct absorption at about  
137  $1600\text{ cm}^{-1}$  is likely due to the presence of the aromatic carbon ring. The peaks in the  
138 range of  $2800\text{ cm}^{-1}$  to  $3000\text{ cm}^{-1}$  correspond to benzene C-H stretching. Mass spectra  
139 in low ionisation mode (EI, MALDI or FAB) gave either M<sup>+</sup> or (M+1)<sup>+</sup> peaks of  
140 appropriate m/z values with (M-CH<sub>3</sub>)<sup>+</sup> as the common fragment, whereas methoxy  
141 groups were also present. Accurate mass analysis confirmed the expected molecular  
142 formula.

191 2.2. Structural characterization of porous carriers

192 X-ray diffractograms (Figure S3) show that SBA-15 demonstrated three well resolved  
193 peaks, including an intense peak at  $0.86^\circ$  assigned to (10) diffraction, as well as two  
194 weaker peaks at  $1.46^\circ$  and  $1.68^\circ$  which are indexed to (11) and (20) diffractions,  
195 respectively, suggesting long-range order. MCM-41 exhibited four distinct peaks; a  
196 strong peak at  $2.18^\circ$ , which corresponds to (10) diffraction and three weaker peaks at  
197  $3.72^\circ$ ,  $4.28^\circ$  and  $5.72^\circ$ , assigned to (11), (20) and (21) diffractions respectively,  
198 indicating a well-defined hexagonally ordered mesoporous structure. The structural  
199 parameters of the samples are summarized in Table S1. The nitrogen adsorption-  
200 desorption isotherms of both SBA-15 and MCM-41 samples Figure S3 were of type IV  
201 (based on IUPAC classification).

 224 adsorption branch),  $d_{10}$ : d spacing of the (10) reflections deduced from Bragg's equation,  $a_0$ : unit cell parameter for  
 225 hexagonal symmetry according to the equation  $a_0=2 \cdot d_{10}/3^{1/2}$ ,  $t_{wall}$ : pore wall thickness obtained by subtracting pore  
 226 size from the unit cell parameter ( $t_{wall}=a_0-D$ ).

227

### 228 2.3 Preliminary drug concentration determination

229 A preliminary study was conducted to investigate the maximum drug content that can  
 230 be loaded into mesoporous silica in the amorphous state using both loading methods  
 231 (solvent impregnation and electrospraying). XRD was used to evaluate the crystallinity  
 232 of the drug loaded in the different formulations. XRD pattern of KAZ3 was also  
 233 obtained (Figure S4 A) confirming the drug's crystalline nature with four major  
 234 diffraction peaks at 11.7°, 17.3°, 21° and 26.4°.

235 A maximum loading efficiency (35.6 %) was achieved when using drug concentration  
 236 of 2 mg/ml for samples prepared using the solvent impregnation method. However,  
 237 further increasing the drug concentration decreased the encapsulation efficiency.  
 238 EHDA method was able to achieve a high encapsulation efficiency at all tested drug  
 239 concentrations. However, XRD analysis of electrosprayed formulations showed that  
 240 the drug was entrapped in the amorphous form into the pores only when using drug  
 241 concentrations of 2 mg/ml (Figure S4 B). A higher crystallinity in the produced  
 242 formulations was observed by increasing the drug concentration to 6 mg/ml or 9 mg/ml.  
 243 For the solvent impregnation method, increasing the drug concentration more than 2  
 244 mg/ml resulted in an increase in drug crystallinity in the resulting formulations (Figure  
 245 S4 C). It can be concluded that a complete pore filling was achieved when suspending

246 mesoporous silica in drug solution of 2 mg/ml. As a result, 2 mg/ml was chosen as the  
247 initial drug concentration and 25 % w/w was set as a target loading for both loading  
248 methods.

249

250 **Table S2.** Encapsulation efficiency at different drug concentrations and drug to  
251 mesoporous silica ratios for both loading methods.

| <b>Loading Method</b> | <b>Drug concentration (mg/ml)</b> | <b>Drug: SBA-15 (Theoretical loading % w/w)</b> | <b>Encapsulation Efficiency (%)</b> |
|-----------------------|-----------------------------------|---|-------------------------------------|
| Solvent impregnation  | 2                                 | 1:3 (25 %)                                      | 35.6 ± 3.2                          |
| Solvent impregnation  | 6                                 | 1:1 (50 %)                                      | 28.8 ± 0.14                         |
| Solvent impregnation  | 12                                | 2:1 (66.6 %)                                    | 21.0 ± 1.2                          |
| Electrospraying       | 2                                 | 1:3 (25 %)                                      | 91.7 ± 0.4                          |
| Electrospraying       | 6                                 | 1:1 (50 %)                                      | 93.8 ± 16.6                         |
| Electrospraying       | 12                                | 2:1 (66.6 %)                                    | 103.5 ± 6.1                         |

281

282 2.4 SEM

283 SEM images of the pristine silica particles and the prepared formulations are shown in  
284 Figure S5. SBA-15 (Figure S5 A) demonstrated rod-like particles with a diameter of  
285 approximately 0.45  $\mu\text{m}$  and a length of  $\sim 1.1 \mu\text{m}$ . The resulting particulates showed an  
286 affinity to form longer fiber-like structures with lengths up to 10 - 22  $\mu\text{m}$ . MCM-41  
287 (Figure S5 F) exhibited compact, rough and irregular shaped particles (0.5-1  $\mu\text{m}$ ), as  
288 well as fiber-like structures, as in the case of pristine SBA-15. Non-porous FS (Figure  
289 S5 K) consisted of small irregular shaped particles (0.1 - 0.5  $\mu\text{m}$ ) that tend to  
290 agglomerate into coarse spherical clumps.

298

299

300 2.5 Particle size distribution

301 Particle size distributions of the silica materials before and after drug loading are shown  
302 in Figure S6, while the corresponding data (including average particle size and span  
303 value) are given in Table S3. Particle size deduced from DLS analysis appeared smaller  
304 compared to that obtained using SEM, which is most likely due to the sonication  
305 process performed prior to DLS measurements. The results demonstrated that  
306 electrospayed mesoporous silica particles (SBA-15 and MCM-41) are nearly uniform  
307 in size (span  $\leq 0.073$ ) exhibiting smaller particle sizes than raw silica, effect attributed  
308 to the impact of atomization of merged fiber-like structures. The mean particle size of  
309 pristine SBA-15 and MCM-41 was 1231 and 1611 nm, respectively, whereas for  
310 electrospayed formulations (e.g. SBA-Eth-SP and MCM-Eth-SP), the mean particle  
311 size was 535 and 409 nm, respectively. However, the size of electrospayed non-porous  
312 silica formulations (e.g. FS-AC-SP) appeared to be greater than raw particles due to the  
313 presence of the dispersed drug crystals, which enhanced particle cohesiveness.  
314 Formulations prepared using solvent impregnation (SBA-Eth-SIM, MCM-Eth-SIM  
315 and FS-AC-SIM) exhibited increased mean particle sizes of 2091, 2463 and 2496 nm,  
316 respectively. In addition, the values D90 of for these particles were 6085, 6811 and  
317 7100 nm, respectively. This increase in particle size and polydispersity (span value  $\leq$   
318 59.9) is attributed to the presence of aggregated particle clusters.

371

372

373

374 2.6  $\zeta$ -potential studies

375 Plain SBA-15, MCM-41 and FS nanoparticles exhibited negative zeta potential owing  
376 to the negatively charged silanol groups (SI, Table S4). The  $\zeta$ -potential values of SBA-  
377 15 and MCM-41 nanoparticles were highly negative (-42.64 mV and -54.86 mV,  
378 respectively), compared to that of the non-porous FS material (-34.08 mV) [1]. This is  
379 attributed to the greater surface area of their mesostructure and thus greater exposure to  
380 silanol groups of SBA-15 and MCM-41, when compared to non-porous FS. This  
381 suggests that SBA-15 and MCM-41 are highly reactive owing to the large number of  
382 surface accessible silanol groups, which are able to electrostatically interact with more  
383 drug molecules, hence achieving high drug loading [1]. KAZ3 loading increased the  $\zeta$ -  
384 potential values of all formulations but with variations arising due to the encapsulation  
385 method. This might be attributed to the interaction of silica's silanol groups with the  
386 positively charged drug molecules. KAZ3 loading on MCM-41 particles using the  
387 solvent impregnation technique resulted to an increase in  $\zeta$ -potential from -54.80 mV  
388 to -22.70 mV, whereas the use of electrospraying technique further increased the  $\zeta$ -  
389 potential values of the particles up to 27.26 mV, suggesting a greater interaction  
390 between the drug and silanol moieties when compared to the solvent impregnation  
391 method. Similar increase in  $\zeta$ - potential of mesoporous silica particles upon drug  
392 loading has been reported previously [2].

397

398

399

400 **Table S4.**  $\zeta$ -potential of the different types of silica particle dispersions in different  
 401 solvents.

| Silica type | Solvent | $\zeta$ -potential of dispersion | Stability of dispersion* |
|-------------|---------|----------------------------------|--------------------------|
| SBA-15      | Acetone | $-9.7 \pm 6.5$                   | Unstable                 |
| SBA-15      | Ethanol | $-32.6 \pm 6.5$                  | Stable                   |
| MCM-41      | Acetone | $-0.9 \pm 6.4$                   | Unstable                 |
| MCM-41      | Ethanol | $-50.7 \pm 4.5$                  | Stable                   |
| FS          | Acetone | $-36.7 \pm 12.5$                 | Stable                   |
| FS          | Ethanol | $-35.6 \pm 9.1$                  | Stable                   |

402 SBA: SBA-15, MCM: MCM-41, FS: fumed silica, Eth: Ethanol, AC: acetone, SIM: solvent impregnation method  
 403 and SP: electrospraying method \* The separating line between stable and unstable dispersions is normally taken at  
 404 either +30 or -30 mV. Dispersions with  $\zeta$ -potential beyond the range of  $\pm 30$  was considered stable.

405

## 406 2.7 FTIR studies

407 FTIR analysis was performed to study the effect of drug loading on the chemical  
 408 structure or interactions developed between the drug and silica. FTIR spectra (Figure  
 409 S7) of SBA-15, MCM-41 and FS showed a broad peak at  $3420 \text{ cm}^{-1}$  that corresponds  
 410 to O–H stretching vibration of the free silanol groups, while the intense peak in the  
 411 range of  $1000\text{-}1100 \text{ cm}^{-1}$  is assigned to the stretching vibrations of the Si–O bond [3].  
 412 The FTIR spectra of drug-loaded formulations showed all the characteristic drug peaks  
 413 corresponding to the enone group. This suggests that the chemical structure of KAZ3  
 414 is not affected by the electrospraying process. Nevertheless, the decreased intensity and  
 415 the disappearance of some peaks could be attributed to the dilution effect of silica  
 416 particles. The FTIR spectra of physical mixtures revealed similar trends, confirming  
 417 that the reduced peak intensity is indeed due to the dilution effect of the silica particles.  
 418 The intensities of the peaks corresponding to silanol O–H appear decreased for the

419 atomized drug loaded formulations as shown in the insert (Figure S7), suggesting that  
420 the quantity of free silanol groups has decreased due to their possible interactions with  
421 the drug. The reduction or absence of silanol O–H peak intensity due to its consumption  
422 during the interaction with the loaded drug or surface functional groups has been  
423 previously reported in the literature [4,5].

497 method and SP: electrospraying method

498

499 The shift in drug's melting peak in the physical mixtures from the original drug's  
500 melting peak (101 °C) accounts for the entrapment of drug molecules within silica  
501 mesopores during the melting process of the DSC procedure. In contrast, the  
502 endothermic melting peak shown in thermograms for drug and nonporous silica  
503 physical mixture appears at the value identical to drug's melting temperature. The  
504 decrease in peak sharpness for the three physical mixtures is due to dilution effect of  
505 amorphous silica.

 554 MCM, SBA and FS formulations. Phase contrast microscopic images (32x) of Caco-2  
 555 cell cultures grown **A.** without treatment (control culture) **B.** after treatment with 1 %  
 556 Triton X-100 and **C-N.** after incubation with 0.1 mg/mL and 1 mg/mL of drug loaded  
 557 MCM, SBA and FS materials for 48 h. [MCM-41, SBA-15: mesoporous silica

558 nanoparticles; FS: non porous fumed silica nanoparticles; SP: electrospraying method  
559 for drug loading; SIM: solvent impregnation method for drug loading.
